1. What inspired this project

Loadshedding is over in South Africa, but the outages are not. Eskom has reported more than 500 days without it, yet in the townships the power still cuts out because of load reduction, cable theft and substation faults. In Johannesburg the water fails too: 22 major outages in two weeks of January 2026 alone. When this happens there is no stage or schedule to check. People turn to rumours in WhatsApp groups, while families and spaza shops lose food, stock and income waiting to learn what is real.

We are Tshedza Tshikovhi and Mulanga Munaka, both 22. Tshedza is a software developer who leads a small team at Shudu Connections in The Innovation Hub, building an SME incubation platform, and who built CashCram, a Top-13 finalist in NWU's 2026 Pitch Your Business Competition. Mulanga is a biomedical engineering student at Wits and was responsible for the medical side of the app: the medical power plan, its battery alerts and the emergency features. Her training in designing for real people in high-stakes settings shaped how they work.

Our idea is simple: the people living in a neighbourhood already know what is failing in it. Kasi Grid turns their reports into verified, community-level alerts. An outage counts as verified only when three different devices agree.

2. Problem statement

Loadshedding has officially ended. Eskom reports more than 500 days without it. But in townships and informal settlements, power and water still fail without warning. The causes are load reduction, cable theft and substation faults, and in Johannesburg 22 major water outages hit in just two weeks of January 2026. These failures have no stage and no published schedule, so there is nothing to check. People rely on rumours in WhatsApp groups to learn what is real. The people hurt most are low-income households and spaza shop owners, who lose food, stock and a day's income because they find out too late to prepare. Households that depend on power for oxygen concentrators or other medical devices are at the greatest risk, because they cannot tell how long their battery will last against an outage.

The pain points are specific. There is no trusted, community-level source of what is failing right now. There is no warning before it happens. Rumour spreads faster than any official notice. And the tools that exist assume a signal and a schedule, but signal drops exactly when the power does. The people living in a neighbourhood already know what is failing in it, but nothing turns that knowledge into something others can act on.

There is a quieter problem underneath. Digital life has made it easier to scroll past the person next door. In a blackout people learn what is happening on their own street from rumours in a group chat, not from each other, and a household sitting in the dark often has no idea that a neighbour two doors down has a generator, a gas stove or a spare phone charger. The tools meant to connect us have left many communities less connected, exactly when a community is needed most.

3. Solution and features

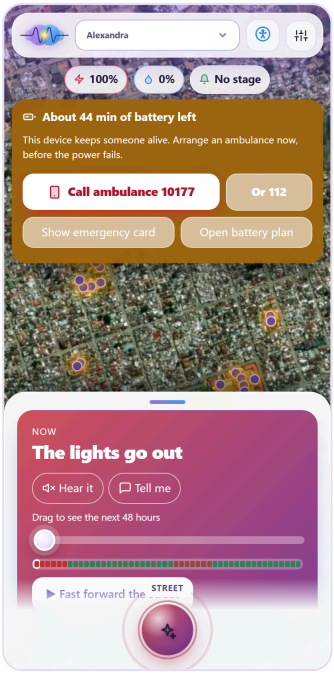

Kasi Grid is a free web app that is named, not anonymous (you look around freely, and sign in to take part so neighbours see who said what), installs on a phone and keeps working offline. It turns neighbours' reports into verified outage alerts for power and water, learns when and how long outages happen, and connects an

outage to action: a medical battery countdown, an ambulance call, help from neighbours and what an outage costs a shop. It works for any place in South Africa.

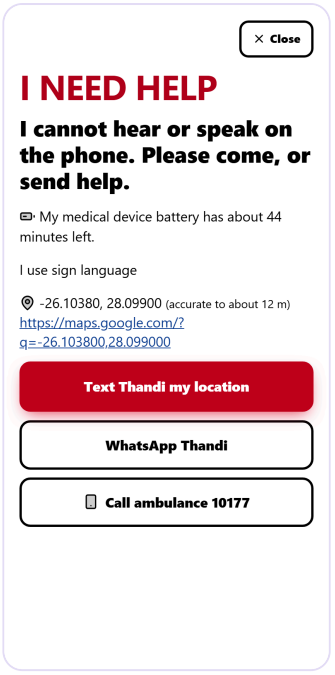

- **A live satellite street.** The home screen is a real satellite view of the community with every mapped home as a glowing dot. Homes go dark as the risk of a power cut rises. Drag a slider through the next 48 hours and watch the street dim and relight. Tap a home for its status.
- **Verified outages.** Three or more different neighbours (three separate accounts) reporting the same problem make a verified outage on the map, and each report shows who made it and who confirmed it. Neighbours vote "back on for me" and the alert closes itself.
- **Real neighbours, real names.** Anyone can look around, the medical battery countdown works with no account, and to report, confirm or offer help you sign in with a free account (cell number or email and a password) and a name your neighbours will see, for example Thandi M. Every report, confirmation and offer shows who said it, so trust is built between people and not hidden behind a screen. Your number or email is never shown. The account also keeps your area, language, accessibility settings and bookings on any phone and signs you in automatically.
- **Anywhere in South Africa.** Every place is a community of about 2 km. Find any town, suburb or street, or use your location. Reports and posts can carry an exact pin; neighbours see board posts only to about 100 m so no home is given away.
- **Early warning.** The app learns each community's own pattern (which weekday and time outages cluster) and how long they last, shows "expected back around 16:30", and says when it does not have enough data.
- **Medical power plan.** A household enters its device and battery; the plan counts the real hours, tracks them live against the time on battery (and against readings from the battery display), alerts at 2 hours, 1 hour, 30 minutes and empty, and puts a call to the ambulance one tap away. A text-my-location emergency card works without a voice call.
- **Care and equipment booking** in four short steps: fixed price, the nearest carers or runners are asked, a prescription check for oxygen.
- **Small business outage cost.** What an outage has cost a shop so far in lost sales and stock at risk, and ranked fixes by payback.
- **Help between neighbours.** A community board for offers and requests (charging, water, lifts, cold storage), restock orders pooled between spazas, nearby shops, clinics and food prices, savings calculators.
- **Built for everyone.** Accessibility settings for people who are deaf, hard of hearing, blind or have low vision (flash, vibration, large-text and spoken alerts, screen-reader announcements, text size, high contrast, reduced motion). Four languages, offline, low data.

4. What makes this solution stand out

Kasi Grid brings a community closer together instead of pulling people apart. Most apps ask you to look at a screen alone. Kasi Grid only works when neighbours take part: an outage is real because three neighbours say so, help reaches a dark home because a neighbour offers it, and a spaza saves money because other spazas order with it. The technology is there to get people talking to the people next door, which is the old township spirit of ubuntu, "I am because we are", in a form that fits a phone.

- **Neighbours make it true.** Three different neighbours must agree before an outage is verified, so the alert is a shared act, not a post you scroll past. Neighbours then vote "back on for me" to close it.
- **Help travels door to door.** A neighbour with a generator, a gas stove or a charger offers it on the community board and shows on the street map as a gold light, with a thread running to the nearest dark home. People who need a lift, water, charging or cold storage for medicine can ask the street.
- **Shops grow together.** Spazas order stock as one group for lower prices, and see what an outage costs them, so a local business is held up by its neighbours.
- **No one is left out.** It works offline and on a basic phone, in four languages, for people who are deaf, hard of hearing, blind or have low vision, so the person who most needs the community is not the person the app forgets.
- **Trust, not rumour.** Because the information comes from real neighbours and is checked by more than one, it replaces the rumour mill with something people can rely on.
- **It protects the most vulnerable.** A live battery countdown and a one-tap ambulance call exist because the people closest to someone on a medical device are their neighbours and family.

5. Unfair advantage

- **A network of neighbours, not a feed.** The product only works when people in a community take part, so each person who joins makes it better for the next, and the trust it builds between neighbours is something a copy of our screens cannot copy.

- **No dependence on anyone else's data.** Loadshedding apps stop working when there is no official schedule. Our source is the neighbours, so the service keeps working where official systems are silent.
- **It still works when the power and signal go.** The app works offline and queues posts until signal returns.
- **The data improves with every report and stays local.** Each verified outage adds to a record of when and how long outages happen in that community. A newcomer can copy our screens but not that history or the trust around it.
- **We are close to the problem.** Two 22-year-old South Africans who live with these outages: a developer who ships, and a biomedical engineering student who knows how people depend on power for health.

6. Customer segments

Segment	Who exactly	Why them
Township households (primary)	Adults 18 to 55 in low-income households (roughly under R10,000 a month) in Gauteng to start, using prepaid electricity and often one shared smartphone on prepaid data.	They feel unscheduled outages first and cannot absorb spoiled food. They need a free, low-data, offline tool in their own language.
Spaza shops and small traders (primary)	Owner-operators aged 25 to 55 with a fridge or freezer and mobile money.	An outage means spoiled stock and lost sales the same day, and buying alone costs more.
Medically dependent households (priority)	Families using oxygen concentrators, nebulisers, CPAP or dialysis at home, and their carers (often an adult child aged 25 to 60).	The stakes are highest: they need to know how long a battery lasts and who to call.
Neighbours who can help (secondary)	People with a generator, solar kit, borehole or car; ward and street committees.	They turn the board into real help and spread the app by trust.
Partners (later)	Equipment suppliers, carers, clinics, wholesalers.	They fulfil requests and give a way to earn without charging households.

Entry point: a few suburbs in Johannesburg first, in English plus the main local languages, then other cities. The first users to reach are spaza owners and community groups, because one shop owner or street committee brings in many households.

7. Key metrics

Targets for a first six-month Johannesburg pilot. They are goals, not results.

Area	Metric and target
Reach	3,000 active users in 10 or more suburbs; 150 spaza shops, 40 in a shared restock order; 100 medically dependent households with a battery plan
Trust and accuracy	85% of verified outages later confirmed as real; median time from first report to verified alert under 20 minutes; 60% of "likely outage" warnings followed by an outage in the stated window
Impact	50% of users who get an early warning take action; spaza owners report spoiled stock down 20%; pooled orders save at least 8%; medical households knew their battery time in 80% of outages

Area	Metric and target
Engagement	40% weekly return; 30% of users have filed a report
Sustainability	At least 3 partners signed; cost per active user under R5 a month

How we measure: built-in analytics that identify no one, a short in-app survey after an outage, and follow-up calls with a sample of spaza owners and medical households.

8. Distribution channels

Kasi Grid is a web app that installs from the browser, with no app store, no download fee and no large download. Users open a link, tap Add to home screen, and it works offline.

- **WhatsApp.** Every verified outage and restock order has a one-tap share button; spaza owners invite other spazas.
- **Spaza shops as local hubs.** A QR code and poster at the counter; the owner has their own reason to promote it (restock savings).
- **Community leaders and groups.** Ward and street committees, community WhatsApp and Facebook groups, churches and stokvels.
- **Carers, clinics and equipment suppliers.** For medically dependent households, the link is handed out with the equipment or at a visit.
- **Community radio** in local languages for people without smartphones or data.
- **Pilot launches in a few suburbs** first, then repeat the approach suburb by suburb.

9. Cost structure

Estimates for a six-month Johannesburg pilot with about 3,000 users. Planning figures, not quotes.

Monthly running cost	Per month
Hosting and database (serverless host, hosted database, backups)	R600
Outage and weather data (EskomSePush API, weather feed)	R500
Domain, monitoring and error tracking	R300
Community moderators (3 people, R1,500 stipend each)	R4,500
Outreach and data (airtime for community champions, printing)	R3,000
Contingency (10%)	R890
Total	about R9,800

One-off cost	Amount
Translation review into local languages	R6,000
Carer and supplier vetting, through a partner	R5,000
POPIA and terms review	R8,000

One-off cost	Amount
Launch posters, QR codes and counter stands	R4,000
Total	R23,000

Six-month total: about R81,800. Cost per user: about R3.30 a month at 3,000 users. Payment fees (about 3% of each booking or restock order) are variable and are paid from the booking fee or supplier commission, so households do not carry them. Founders' time is not costed.

10. Revenue streams

Households pay nothing. Reporting, alerts, forecasts and the medical battery plan stay free, because charging would exclude the people who need it most. The money comes from businesses and partners that gain from the community the app builds.

Stream	Price	Month-6 estimate
Spaza Pro: advanced outage-cost reports and stock alerts	R49 a month	40 paying shops = R1,960
Restock commission: the wholesaler pays a share of pooled orders	4% of order value	40 shops x 2 orders x R2,500 = R200,000, so R8,000
Booking commission: oxygen, battery backups and carers	10% of the booking (about R45 on R450)	60 bookings = R2,700
Partner listing: verified carers, suppliers and clinics	R299 a month	5 partners = R1,495
Sponsorship or municipal dashboard	R3,000 a month	1 sponsor = R3,000
Total		about R17,155 a month

Against running costs of about R9,800 a month, that leaves about R7,000 a month by month 6, enough to cover the one-off costs within about three more months. These are projections that depend on the user targets above; the wholesaler commission and sponsor figure are not yet agreed with anyone.

Source code

The code is not attached to this entry. It is in a public Git repository: https://github.com/Unsolvedstar/Kasi-Grid. The README explains how to run it, and the repository holds the 111 automated tests.
